ABSTRACT
The curation of a knowledge base is a crucial but costly task. In this work, we propose to take advantage of the edit history of the knowledge base in order to learn how to correct constraint violations. Our method is based on rule mining, and uses the edits that solved some violations in the past to infer how to solve similar violations in the present. The experimental evaluation of our method on Wikidata shows significant improvements over baselines.

KEYWORDS
knowledge base; history; data cleaning; rule mining; Wikidata

ACM Reference Format:

1 INTRODUCTION
Knowledge bases (KBs) play a key role in many applications and lay at the core of the Semantic Web. They contain entities (such as persons, cities, etc.) and statements about them (such as relationships between persons, places of residence, etc.). In this work, we focus on RDFS-style KBs, such as Wikidata [38], YAGO [35] or DBpedia [7]. The data quality of a KB is crucial for its usability. However, it is usually very costly to check the correctness of the data, because KBs can be huge (Wikidata, e.g., contains about 50 millions entities). Moreover, KBs are often built using methods that are error-prone. For instance YAGO and DBpedia are automatically extracted from Wikipedia. Wikidata, for its part, is a collaborative KB that anyone can edit, with more than 18,000 active contributors.

A way of avoiding or at least detecting some of the flaws in the data is to impose constraints on the KB. Such constraints can enforce that some information must be present (e.g., ensuring that every human being has a birth date), or that some statements may not occur (e.g., ensuring that a person is not also a city). Constraints are related to, but different from, ontological rules: A constraint imposes a certain condition, whereas an ontological rule infers certain statements. For example, consider a KB that contains the statement "Spinoza is a human being" without knowing any birth date for Spinoza, and consider a rule "All human beings have a birth date". If the rule is taken as an ontological rule, then it would just infer that Spinoza has some birth date. If the rule is taken as a constraint, in contrast, the KB would be considered incorrect. Constraints are thus similar in spirit to database integrity constraints. In practice, constraints often have exceptions. Therefore, it is useful to allow data that does not respect them (in Wikidata, e.g., constraint violations are simply flagged). Nonetheless, by design, most of the constraint violations are not exceptions but actual errors and proposing to repair them is a good starting point when it comes to improving KB quality.

In this paper, we aim at learning how to repair constraint violations. Our goal is to help a KB editor by suggesting how to clean the data locally (providing a solution to a particular constraint violation) or globally (providing rules that can be automatically applied to all constraint violations of a given form once validated by the editor). To do that, we take advantage of the edit history of the KB. We use it to mine correction rules that express how different kinds of constraint violations are usually solved. To the best of our knowledge, this is the first work that builds on past users corrections in order to infer possible new ones. We validate our framework experimentally on Wikidata, for which the whole edit history of more than 700 millions edits is available. Our experiments show substantial improvements over baselines. More concretely, our contributions are as follows:

- a formal definition of the problem of correction rule mining,
- a dataset of more than 67M past corrections for ten different kinds of Wikidata constraints (13k constraints in total),
- a correction rule mining algorithm, together with an implementation for Wikidata, CorHist,
- a suggestion tool for users to correct data based on our mined correction rules,
- an experimental evaluation based both on the prediction of the corrections in the history and on user validation of the suggested local corrections.

2 RELATED WORK
We start with a brief discussion of works relevant to our problem along three axes: constraints for KBs, KB cleaning, and rule learning.

Constraints. Constraints have long been used in databases and KBs to express rules that the data should follow. Databases typically operate under the closed world assumption, where missing facts are considered to be false. This allows for “completeness” constraints such as tuple generating dependencies. KBs, in contrast, operate under the open world assumption, where missing

3 available at https://tools.wmflabs.org/wikidata-game/distributed/#game=43
facts are not necessarily false. They thus classically have only “correction” constraints, such as disjointness or functionality axioms (corresponding to special cases of denial constraints and equality generating dependencies in databases).

To express also completeness constraints, several works propose to use description logics, with varying semantics [28, 37]. Another possibility is to use queries that should or should not hold as constraints (see e.g., [24] for methods for writing constraint queries in SPARQL). Other approaches define constraint languages to specify conditions for RDF graph [9] validation, such as SHACL [22] or ShEx [8]. It has been argued in [30] that description logics under the closed world assumption are also suitable for constraint checking in RDF, which can then be implemented with SPARQL queries. In our work, we follow a similar path, using description logic axioms as constraints for RDFS KBs, because it corresponds best to what we observe in current real-world KBs.

Contrary to the above works, we do not aim at expressing constraints, but at repairing their violations. The correction rules we learn for this purpose are similar in spirit to active integrity constraints [11], which specify for each constraint a set of possible repair actions. This type of constraints has recently been applied to description logic KBs as well [32]. Conditioned active integrity constraints add conditions for choosing among the possible actions, and we propose, in a similar spirit, to take into account the context of the constraint violation to correct it. Different from the existing work [11, 32], our goal is to mine correction rules automatically from the edit history of the KB.

Knowledge base cleaning. Several recent approaches have dealt with the interactive cleaning of KBs. The proposed methods detect when a constraint is violated, compute the responsible facts, and then interact with the user to find out how to update the KB. The goal is then to minimize the number of questions the user has to answer. This is done in various ways, which include taking into account the dependencies among the facts to check or the interaction between several constraints violations to define heuristics to choose the best question to ask the user [2, 3, 5, 6].

Other approaches to improve the quality of a KB rely on statistics, clustering, or structural aspects of the KBs. The work of [31] uses statistics to add missing types to the KB, and to detect wrong statements. The work of [25] exploits the observation that cycles in the KB often contain wrong “IsA” relations. Again other approaches [1] use crowdsourcing to detect Linked Data quality issues. We refer the reader to Section 7.2 of [1] for a recent overview of approaches for data quality assessment.

Our method also exploits KB constraints. However, it differs from the above in that it learns the corrections automatically from the edit history. It thus taps a source of knowledge that has so far not been exploited.

Rule learning. Mining logical rules by finding correlations in a dataset is a well-established research topic. In particular, learning patterns in the data can be used for completing KBs [14, 36]. An algorithm for learning conjunctive patterns from a KB enriched with a set of rules is described in [20]. Methods similar to association rule mining have also been used for induction of new ontological rules from a KB [33]. A more recent trend is to use embedding-based models for KB completion. A comparison between these models and usual rule learning approaches is reported in [27] and significant recent works in this area include [19, 39, 40].

In this paper, we use a vanilla rule mining algorithm inspired by [14]. Our contribution is not the rule mining per se, but the application of rule mining to the edit history of a KB in order to mine correction rules. This avenue has, to the best of our knowledge, never been investigated.

3 PRELIMINARIES

In this work, we use description logics (DL) [4] as KB language and as constraint language, because they are the foundation of the Semantic Web standard OWL [16].

Syntax. We assume a set NC of concept names (unary predicates, also called classes), a set NR of role names (binary predicates, also called properties), and a set NI of individuals (also called constants). An ABox (dataset) is a set of concept or role assertions of the form $A(a)$ or $R(a, b)$, where $A \in N_C$, $R \in N_R$, $a, b \in N_I$. A TBox (ontology) is a set of axioms whose form depends on the DL $L$ in question, and expresses relationships between concepts and roles (e.g., concept or role hierarchies, role domains and ranges...). A knowledge base (KB) $K = T \cup A$ is the union of an ABox $A$ and a TBox $T$.

In this work, we assume that $T$ is a flat QL TBox [23], i.e., that $L$ differs from the standard RDF Schema (RDFS) [17] only by allowing inverse roles in role inclusions. More precisely, $T$ can contain concept inclusions of the form $A_1 \sqsubseteq A_2$ (subclass), $\exists P \sqsubseteq A$ (domain or range), and role inclusions $P_1 \sqsubseteq P_2$ (subproperty), where $A_1 \in N_C$ and $P_i$ ($i = 1, 2$) \sqsubseteq R \sqsubseteq R^-$ with $R \in N_R$.

A KB can also be written as a set of RDF triples $(s, p, o)$ where $s$ is the subject, $p$ is the property, and $o$ the object, using special properties to translate concept membership and relationships between concepts and roles [29]. A concept assertion $A(a)$ is written as $(a, RDF::type, A)$, and a role assertion $R(a, b)$ as $(a, R, b)$. Flat QL TBox axioms can also be represented by single triples. For example, $A_1 \sqsubseteq A_2$ is written as $(A_1, RDF::subClassOf, A_2)$ and $\exists R \sqsubseteq A$ is written as $(R, RDF::range, A)$.

Semantics. We recall the standard semantics of DL KBs. An interpretation has the form $I = (\Delta^I, \mathcal{F}^I)$, where $\Delta^I$ is a non-empty set and $\mathcal{F}^I$ is a function that injectively maps each an $a \in N_I$ to $a^I \in \Delta^I$ (unique name assumption), $\top \subseteq \Delta^I$, each $A \in N_C$ to $A^I \subseteq \Delta^I$, and each $R \in N_R$ to $R^I \subseteq \Delta^I \times \Delta^I$. The function $\mathcal{F}^I$ is straightforwardly extended to general concepts and roles, e.g., $\neg B^I = \Delta^I \setminus B^I$, $(\top)^I = \emptyset$, and $\{c \mid (d, c) \in \mathcal{F}^I(c, d)\}$, $\{a_1, \ldots, a_n\} = \{a_1^I, \ldots, a_n^I\}$, $(\exists P \cdot B)^I = \{c \mid \exists d : (c, d) \in P^I, d \in B^I\}$, $(\exists \top \cdot \exists P)^I = \{\top^I \cap \exists P^I\} = B^I \cap \exists P^I$, $B_1 \cup B_2^I$ $B_1^I \cup B_2$ $B_1^I \cup B_2^I$. An interpretation $I$ satisfies an inclusion $G \subseteq H$ if $G^I \subseteq H^I$; it satisfies an axiom (func $P$) if $P^I$ is transitive; and it satisfies an axiom (trans $P$) if $P^I$ is transitive and it satisfies $A(a)$ (resp. $R(a, b)$), if $a^I \in A^I$ (resp. $a^I, b^I \in R^I$). We write $I \models a$ if $I$ satisfies the DL axiom $a$.

An interpretation $I$ is a model of $K = T \cup A$ if $I$ satisfies all axioms in $K$. A KB $K$ entails a DL axiom $a$ if $I \models a$ for every model $I$ of $K$.

Queries. A conjunctive query (CQ) takes the form $q(x) = \exists y q'(x, y)$, where $q'$ is a conjunction of atoms of the form $A(t)$ or $R(t, t')$ or of equalities $t = t'$, where $t, t'$ are individual names or variables from
\[ \mathcal{F} \cup \mathcal{G} \] for which \( \mathcal{F} = \emptyset, q \) is a Boolean CQ (BCQ). A BCQ \( q \) is satisfied by an interpretation \( I \), written \( I \models q \), if there is a homomorphism \( \pi \) mapping the variables and individual names of \( q \) into \( \mathcal{F}^\pi \) such that: \( \pi(a) = a^I \) for every \( a \in N_1 \), \( \pi(t) = a^I \) for every concept atom \( A(t) \) in \( \psi \), \( \pi(t), \pi(t') \in R^I \) for every role atom \( R(t, t') \) in \( \psi \), and \( \pi(t) = \pi(t') \) for every \( t = t' \) in \( \psi \). We also consider as BCQs the queries true and false which are respectively always and never satisfied by an interpretation. A BCQ \( q \) is entailed from \( \mathcal{K} \), written \( \mathcal{K} \models q \), if \( q \) is satisfied by every model of \( \mathcal{K} \). A tuple of constants \( \bar{a} \) is a (certain) answer to a CQ \( q(\mathcal{F}) \) if \( \mathcal{K} \models q(\bar{a}) \) where \( q(\bar{a}) \) is the BCQ obtained by replacing the variables from \( \mathcal{F} \) by the constants \( \bar{a} \). We denote by \( \text{answers}(q(\mathcal{F}), \mathcal{K}) \) the set of answers of \( q(\mathcal{F}) \) over \( \mathcal{K} \). A union of BCQs (UCQ) is a disjunction of BCQs and has as answers the union of the answers of the BCQs it contains.

**Canonical model.** It is well-known that a flat QL KB \( \mathcal{K} \) has a canonical model \( I_\mathcal{K} \) such that for every BCQ \( q, \mathcal{K} \models q \) if and only if \( I_\mathcal{K} \models q \). The domain of \( I_\mathcal{K} \) is the set of individual names that occur in \( \mathcal{K} \) and \( A^{I_\mathcal{K}} = \{ a \mid A \models A(a) \} \) for every \( A \in N_2 \) and \( R^{I_\mathcal{K}} = \{ (a, b) \mid A \models R(a, b) \} \) for every \( R \in N_R \) [23].

## 4 CONSTRAINTS

This section defines the constraints that can be imposed on a KB, and relates the problem of checking that a KB complies with these constraints to CQ answering over this KB.

**Defining constraints.** In this work, we consider two types of constraints: consistency constraints (which express that some statements are contradictory), and completeness constraints (which impose that certain statements should hold in the KB as soon as some others do). While violations of consistency constraints can only be solved by removing statements, those of completeness constraints can also be solved by adding statements.

**Definition 1 (Constraint):** Constraints are built from complex concepts and rules defined by the following grammar rules:

\[ P := R \mid R^\pi \]

\[ B := \top \mid A \mid B \land B \mid B \lor B \mid \exists P \cdot \{ a_1, \ldots, a_n \} \mid \exists P \cdot B \]

where \( R \in N_R, A \in N_C, a_1, \ldots, a_n \in N_I \).

A consistency constraint is a concept inclusion of the form \( B_1 \subseteq \neg B_2 \) or of the form \( B \subseteq \{ a_1, \ldots, a_n \} \), a role inclusion of the form \( P_1 \subseteq \neg P_2 \), or a functionality axiom of the form \( \psi \) (func \( P \)).

A completeness constraint is a concept inclusion of the form \( B_1 \subseteq B_2 \), a role inclusion of the form \( P_1 \subseteq P_2 \), or a transitivity axiom of the form \( \psi \) (trans \( P \)).

This definition of constraints covers the “constraining” versions of the majority of the most popular DL axioms used on the Web of Data according to the ranking done by [15].

We assume without loss of generality that concepts of the form \( B_1 \sqcup B_2 \) or \( \{ a_1, \ldots, a_n \} \) with \( n > 1 \) appear only on the right side of inclusions, and not at all in negative inclusions of the form \( B_1 \subseteq \neg B_2 \). For example, we assume that \( \exists P \cdot (B_1 \sqcup B_2) \subseteq C \) is rewritten as \( \exists P \cdot B_1 \subseteq C, \exists P \cdot B_2 \subseteq C, \text{ and } B \subseteq \neg \exists P \cdot \{ a_1, \ldots, a_n \} \) is rewritten as \( B \subseteq \neg \exists P \cdot \{ a_1, \ldots, a_n \} \subseteq \neg \exists P \cdot \{ a_1, \ldots, a_n \} \). As usual, we abbreviate \( \exists P \cdot \top \) as \( \exists P \).

**Example 1:** As a running example, we consider the following KB \( \mathcal{K} = \mathcal{T} \cup \mathcal{A} \) and set of constraints \( C \) inspired from Wikidata. Our TBox \( \mathcal{T} \) expresses that human beings and deities are persons. Our ABox \( \mathcal{A} \) provides information on several individuals. Our constraints \( C \) state that there are three possible genders (consistency constraint), that those who have a mother or are a mother must be persons or animals, that a mother must have gender female, and that if a has mother \( b \), then \( b \) must have child (completeness constraints).

\[ \mathcal{T} = \{ \text{Human} \subseteq \text{Person}, \text{Deity} \subseteq \text{Person} \} \]

\[ \mathcal{A} = \{ \text{Deity(Zeus)}, \text{Deity(Rhea)}, \text{hasGender(Zeus, masculine)}, \]

\[ \text{hasGender(Rhea, female)}, \text{hasMother(Zeus, Rhea)}, \]

\[ \text{hasChild(Rhea, Zeus), \text{Human(Spinosa)}}, \]

\[ \text{hasMother(Spinosa, Marques)} \} \]

\[ C = \{ \Gamma_0 = \exists \text{hasGender} \subseteq \{ \text{male, female, nonbinary} \}, \]

\[ \Gamma_1 = \exists \text{hasMother} \subseteq \text{Person} \sqcup \text{Animal}, \]

\[ \Gamma_2 = \exists \text{hasMother} \subseteq \text{Person} \sqcup \text{Animal}, \]

\[ \Gamma_3 = \exists \text{hasMother} \subseteq \exists \text{hasGender} \cdot \{ \text{female} \}, \]

\[ \Gamma_4 = \exists \text{hasMother} \subseteq \exists \text{hasChild} \} \]
The following proposition shows that this transformation is sound and that the rule body and head can be rewritten as CQ and UCQ.

**Proposition 1:** For every constraint \( \Gamma \in C \), \( \pi(\Gamma) \) can be rewritten as a rule \( \Gamma(x) \) as a constraint \( h(x) \) is a CQ, \( h(x) \) is a UCQ, and for every flat QL KB \( \mathcal{K} \), \( \Gamma \) satisfies \( \pi \) iff answers(\( h(x), \mathcal{K} \)) \( \subseteq \) answers(h(x), \( \mathcal{K} \)).

**Proof:** By our assumptions on the form of the concepts that occur in the left side of the inclusions or in the right side of a negative inclusion, \( b(x) := \exists y q(x, y) \) is a CQ. It is easy to show by structural induction that for every concept B (resp. role P), \( \pi(B, x) \) (resp. \( \pi(P, x, y) \)) can be written as a UCQ \( q(x) \) (resp. \( q(x, y) \)) and that answers(\( q(x), \mathcal{K} \)) = \( B^{\mathcal{K}} \) (resp. answers(\( q(x, y), \mathcal{K} \)) = \( P^{\mathcal{K}} \)). If \( \Gamma \) is a completeness constraint of the form \( B_1 \subseteq B_2 \) (resp. \( P_1 \subseteq P_2 \)), or a consistency constraint of the form \( B \subseteq \{ a_1, \ldots, a_n \} \), the result follows immediately since \( \mathcal{K} \) satisfies \( \pi \) iff \( \text{In}_{\mathcal{K}} \models \Gamma \). If \( \Gamma \) is a consistency constraint of the form \( B_1 \subseteq \neg B_2 \) (resp. \( P_1 \subseteq \neg P_2 \)), answers(\( b(x, \mathcal{K}) \)) = \( B^{\mathcal{K}}_1 \cap B^{\mathcal{K}}_2 \) (resp. answers(\( b(x, \mathcal{K}) \)) = \( P^{\mathcal{K}}_1 \cap P^{\mathcal{K}}_2 \)) and is empty iff \( \Gamma \) is satisfied. Since in this case \( h(x) := false \), answers(h(x), \( \mathcal{K} \)) = \( \emptyset \), and the desired relation holds.

If \( \Gamma \) is of the form (func \( P \)), since the answers of h(x, y, z) := y = z over \( \mathcal{K} \) are all possible tuples of the form (\( a, b, b \)), \( P^{\mathcal{K}} \) is functional iff answers(\( b(x, y, z), \mathcal{K} \)) \( \subseteq \) answers(\( h(x, y, z), \mathcal{K} \)). Finally, if \( \Gamma \) is of the form (trans \( P \)), \( b(x, y, z) := \pi(P, x, y) \land \pi(P, y, z) \) and \( h(x, y, z) := \pi(P, x, z) \), and it is easy to see that \( P^{\mathcal{K}} \) is transitive iff answers(\( b(x, y, z), \mathcal{K} \)) \( \subseteq \) answers(\( h(x, y, z), \mathcal{K} \)).

**Constraint violations.** A constraint instance \( \Gamma(\bar{a}) \) of a constraint \( \Gamma(x) \) is obtained by replacing the variables \( \bar{x} \) by the individual names \( \bar{a} \) in \( \Gamma(\bar{x}) \). This notion allows us to define constraint violations:

**Definition 2 (Constraint violation):** A violation of a constraint \( \Gamma(\bar{x}) \) in \( \mathcal{K} \) is a minimal subset \( \mathcal{V} \subseteq \mathcal{K} \) such that there exists \( \bar{a} \) such that \( \mathcal{V} \) violates \( \Gamma(\bar{a}) \) and \( \mathcal{K} \) violates \( \Gamma(\bar{a}) \). We denote by Violations(\( \mathcal{K}, \Gamma(\bar{x}) \)) the set of violations of \( \Gamma(\bar{x}) \).

In this definition, the requirement that \( \mathcal{K} \) violates \( \Gamma(\bar{a}) \) may seem superfluous. Yet, if \( \Gamma \) is a completeness constraint, it may be the case that some \( \mathcal{V} \subseteq \mathcal{K} \) violates \( \Gamma(\bar{a}) \), while \( \mathcal{K} \) satisfies it.

**Example 4:** In our running example, it is easy to see that the subset \( \mathcal{V}_6 = \{ \text{hasGender}(\text{Zeus}, \text{masculine}) \} \) is a violation of \( \Gamma_6 \). Consider now \( \mathcal{V} = \{ \text{hasMother}(\text{Spinossa}, \text{Marques}) \} \). \( \mathcal{V} \) is a violation of \( \Gamma_2, \Gamma_3 \) and \( \Gamma_4 \). Indeed, it violates \( \Gamma_2, \Gamma_3 \) and \( \Gamma_4 \) of (Spinossa, Marques) and \( \mathcal{K} \) satisfies any of these constraint instances. However, even if \( \mathcal{V} \) violates \( \Gamma_1 \), \( \mathcal{V} \) is not a violation of \( \Gamma_1 \) because \{Human(Spinossa),Human \( \sqsubseteq \) Person\} \( \subseteq \mathcal{K} \) satisfies the head of \( \Gamma_1 \) (Spinossa).

If a constraint instance \( \Gamma(\bar{a}) \) is violated, \( \bar{a} \in \text{answers}(h(\bar{x}), \mathcal{K}) \) and \( \bar{a} \notin \text{answers}(h(\bar{x}), \mathcal{K}) \), so its violations are the minimal subsets \( \mathcal{K} \) responsible for \( \bar{a} \in \text{answers}(h(\bar{x}), \mathcal{K}) \). The next proposition relates constraint violations and justifications. A justification (also known as an explanation, axiom pinpointing, or MinAs) for the entailment of a BCQ is a minimal subset of the KB that entails the BCQ [21, 34].

**Proposition 2:** If \( \mathcal{V} \) violates \( \Gamma(\bar{a}) : b(\bar{a}) \rightarrow h(\bar{x}) \), a subset \( \mathcal{V} \subseteq \mathcal{K} \) is a violation of \( \Gamma(\bar{a}) \) iff \( \mathcal{V} \) is a justification of \( \mathcal{K} \models b(\bar{a}) \).

**5 CORRECTIONS**

We now turn to correcting constraint violations.

**Solutions.** We will make use of atomic modifications of the KB to define solutions to constraint violations.

**Definition 3 (Atomic modification):** An atomic modification of a KB \( \mathcal{K} \) is a pair \( m = (\mathcal{M}^+, \mathcal{M}^-) \) of two sets of assertions or \( \mathcal{L} \)-axioms that takes one of the following forms:

- Addition: \( m = \{ (\langle s, p, o \rangle), \emptyset \} \), where \( (s, p, o) \notin \mathcal{K} \)
- Deletion: \( m = \{ (\emptyset, (s, p, o)) \} \), where \( (s, p, o) \in \mathcal{K} \)
- Replacement: \( m = \{ (\langle s, p, o \rangle), (\langle s', p', o' \rangle) \} \), where \( (s, p, o) \notin \mathcal{K} \), \( (s', p', o') \in \mathcal{K} \), and \( (s, p, o) \) differs from \( (s', p', o') \) in exactly one component.

Thus, an atomic modification consists of two sets \( \mathcal{M}^+, \mathcal{M}^- \), each of which is either the empty set or a singleton set. \( \mathcal{M}^+ \) will be added to the KB, and \( \mathcal{M}^- \) will be removed from the KB. Since the sets contain at most one triple, we slightly abuse the notation and identify the singletons with their elements (e.g., we will denote the addition of \( \langle s, p, o \rangle \) simply by \( (s, p, o) \)). A replacement is equivalent to a sequence of a deletion and an addition. We chose to keep it as an atomic modification because it corresponds to common knowledge base curation tasks, such as correcting an erroneous object for a given subject and predicate, or fixing a predicate misuse. Atomic modifications can be used to solve a constraint violation, as follows:

**Definition 4 (Solution):** A solution to a violation \( \mathcal{V} \) of a constraint instance \( \Gamma(\bar{a}) \) in \( \mathcal{K} \) is an atomic modification \( (\mathcal{M}^+, \mathcal{M}^-) \) such that there exists \( \mathcal{K}' \subseteq \mathcal{K} \) such that \( \mathcal{V} \subseteq \mathcal{K} \) \( \setminus \mathcal{K}' \) of \( \mathcal{M}^+ \) satisfies \( \Gamma(\bar{a}) \).

We call \( (\mathcal{M}^+, \mathcal{M}^-) \) a solution to \( \mathcal{V} \) for \( \Gamma(\bar{a}) \) in \( \mathcal{K} \).

Note that \( \Gamma(\bar{a}) \) can still be violated in \( \mathcal{K} \setminus \mathcal{K}' \) if \( \mathcal{K} \) contains other violations of \( \Gamma(\bar{a}) \) for which \( \mathcal{M}^+ \) is not a solution. For example, if \( \Gamma(\bar{a}) : \exists x r(a, x) \land A(a) \rightarrow false \), and \( \mathcal{K} = \{ r(a, b), r(a, c), A(a) \} \), the deletion of \( r(a, b) \) is a solution to the violation \( \{ r(a, b), A(a) \} \), but \( \{ r(a, c), A(a) \} \) still violates \( \Gamma(\bar{a}) \). Note also that every constraint violation has at least one solution, which consists of the deletion of any of its elements. Solutions may also be additions or replacements, as in the following example:

**Example 5:** In our running example, the deletion (\( \emptyset \), hasGender (Zeus, masculine)) and the replacement (hasGender(Zeus, male),...
We also prefer replacements over deletions as long as they fulfill the constraint violations. The edit history allows us to pinpoint how constraint violations have been corrected in the past. In order to avoid learning from the KB modifications to learn how to correct constraint violations. The following definition formalizes these requirements.

**Definition 7 (Relevant Past Correction):** A relevant past correction \((M^+, M^-)\) to a violation \(V\) of a constraint instance \(\Gamma(d)\) in \(K\) is a past correction such that (i) \(M^+ \sqcup M^-\) contains only assertions, and (ii) \((V \cup A_1) \cup T_P\) contains a violation \(V'\) of \(\Gamma(d)\) such that \((M^+, M^-)\) is also a solution to \(V'\) in \(A_1 \cup T_P\).

We will now see how we can use the relevant past corrections to mine correction rules.

### 6 FROM HISTORY TO CORRECTION RULES

In this section, we propose an approach based on rule mining to learn correction rules for building solutions to constraint violations.

#### 6.1 Extraction of the Relevant Past Corrections

Algorithm 1 constructs the set of relevant past corrections from the KB history. It consists of three main steps. First, it constructs patterns to spot KB modifications that could be part of a relevant past correction. Then it uses these patterns to extract atomic modifications that solved some violation in the past. Finally, the relevant past corrections are obtained by pruning those that have been reversed.

**Algorithm 1 Construction of PCDataset**

**Input:** set of constraints \(C\), current TBox \(T_P\), history \((K_i)_{0 \leq i \leq p}\)

**Output:** set of relevant past corrections PCDataset

// Construct correction seed patterns
for all \(\Gamma \in C\) such that \(\Gamma(\xi) : b(\xi) \rightarrow h(\xi)\) do
- Patterns(\(\Gamma\)) := \{(\_ , \_A(\xi)) | A(\xi) \in b'(\xi), b'(\xi) \in rewrite(b(\xi), T_P))\}
if \(\Gamma\) is a completeness constraint then
- Patterns(\(\Gamma\)) := \{(\_A(\xi), \_x) | A(\xi) \in h'(\xi), h'(\xi) \in rewrite(h(\xi), T_P))\}

// Extract past corrections
for \(0 \leq i \leq p - 1\) do
if \((M^+_i, M^-_i)\) such that \(K_{i+1} = (K_i \cup M^+_i) \setminus M^-_i\) matches some pattern in Patterns(\(\Gamma\)) then
- PCDataset := \{((M^+_i, M^-_i), \Gamma(\xi), V, i) | \(V\) in Violations(K_i, \(\Gamma(\xi)\)) \}
// Remove reversed past corrections
for \(((M^+_i, M^-_i), \Gamma(\xi), V, i)\) in PCDataset do
if \(M^+_i \not\subseteq K_P\) or \(M^-_i \not\subseteq K_P\) then
- PCDataset := \{((M^+_i, M^-_i), \Gamma(\xi), V, i)\}

Let us explain our algorithm with our running example. Consider the constraint \(I_0(x) : \exists y\text{hasGender}(y, x) \rightarrow x = \text{male} \lor x = \text{female} \lor x = \text{nonbinary}\). Assume that \((Zeus, \text{hasGender, masculine})\) was added between \(K_1\) and \(K_2\), but then replaced by \((Zeus, \text{hasGender, male})\) between \(K_{100}\) and \(K_{101}\).

The first goal of the algorithm is to find out that the removal of \((Zeus, \text{hasGender, masculine})\) between \(K_{100}\) and \(K_{101}\) (as part of the replacement) may be part of a relevant past correction. We call this deletion a correction seed. Formally, a correction seed is a deletion \((\emptyset, M^-)\) or an addition \((M^+, \emptyset)\) such that \(i\) there exists \(0 \leq i \leq p - 1\) such that \(K_{i+1} = (K_i \cup M^+_i) \setminus M^-_i\) with \(M^+_i = M^-_i\).
We collect the patterns for the constraint \(\Gamma\) which is not in \(\mathcal{K}_0\) (resp. \(\mathcal{M}^+\)) via CQ answering (Proposition 1), and computing their violations for all constraints on all KB versions has the advantage of significantly reducing the search space.

To find such correction seeds efficiently, the first step of the algorithm precomputes for each constraint a set of atomic modification patterns that the possible correction seeds would match. In the example there would be only one pattern: the deletion pattern \(\langle., ?, \text{hasGender}, ? \rangle\), where \(c\) can be anything so that it matches both the deletion of \(\langle., ?, \text{hasGender}, ? \rangle\) and its replacements. So we only consider past corrections that involve assertions, and want them to be relevant for the current TBox. Computing the correction seed patterns can be done via query rewriting of the CQs in the body \(b(\bar{x})\) and the head \(h(\bar{x})\) of the constraint w.r.t. \(\mathcal{T}_p\). Indeed, if \(\mathcal{T}\) is a flat QL TBox, any CQ \(q(\bar{x})\) can be rewritten w.r.t. \(\mathcal{T}\) into a UCQ \(q'(\bar{x})\) such that for every ABox \(\mathcal{A}\), answering \(q(\bar{x})\) over \(\mathcal{T}\) \(\cup\mathcal{A}\) amounts to answering \(q'(\bar{x})\) over \(\mathcal{A}\) [23]. Each atom that occurs in the rewriting of the body of a constraint corresponds to a deletion pattern, and each atom that occurs in the rewriting of the head of a completeness constraint corresponds to an addition pattern. We collect the patterns for the constraint \(\Gamma\) in the set \(\mathcal{P}(\Gamma)\). Note that it is not possible to solve a consistency constraint with an addition, which is why such constraints have only deletion patterns.

The second step of the algorithm verifies, for each correction seed, whether it solved some constraint violation in the past – i.e., whether \(\mathcal{K}_i\) contains some violations of some constraint instances that are not in \(\mathcal{K}_{i+1}\). If so, the modification between \(\mathcal{K}_i\) and \(\mathcal{K}_{i+1}\) is a solution that solved these violations in \(\mathcal{K}_i\). In the example we would have found the violation \(\langle\langle \text{Zeus}, \text{hasGender}, \text{male} \rangle, \langle \text{Zeus}, \text{hasGender}, \text{masculine} \rangle \rangle\) of \(\mathcal{I}_0(\text{masculine})\) in \(\mathcal{K}_{100}\), which is not in \(\mathcal{K}_{101}\). So we would have extracted that \(\langle\langle \text{Zeus}, \text{hasGender}, \text{male} \rangle, \langle \text{Zeus}, \text{hasGender}, \text{masculine} \rangle \rangle\) is a solution that solved the violation \(\langle\langle \text{Zeus}, \text{hasGender}, \text{masculine} \rangle, \langle \text{Zeus}, \text{hasGender}, \text{male} \rangle \rangle\) of \(\mathcal{I}_0(\text{masculine})\) in \(\mathcal{K}_{100}\). We store this information as a tuple in the relevant past corrections dataset (the PCDataset), as shown in Table 2. Finding the constraint instances violated in \(\mathcal{K}_i\) or \(\mathcal{K}_{i+1}\) is done via CQ answering (Proposition 1), and computing their violations amounts to computing BCJ justifications (Proposition 2).

The final step of the algorithm removes corrections that have been reversed. The result is thus the set of relevant past corrections.

### 6.2 Correction Rule Mining

**Correction rules.** The previous algorithm has given us a list of relevant past corrections (the PCDataset, exemplified in Table 2). We now present our approach to mine correction rules from this dataset and the KB history.

**Definition 8** (Correction rule): A correction rule is of the form

\[ r := [\Gamma(\bar{x})] : E(\bar{x}, \bar{y}, \bar{z}) \rightarrow (M^+(\bar{x}, \bar{y}), M^-(\bar{x}, \bar{y})), \text{ where} \]

- \(\Gamma(\bar{x})\) is a constraint that can be partially instantiated, i.e., some of its variables have been replaced by constants,
- \((M^+(\bar{x}, \bar{y}), M^-(\bar{x}, \bar{y}))\) is a pair of sets of at most one triple,
- \(E(\bar{x}, \bar{y}, \bar{z})\) is a set of atoms called the context of the violation such that \(M^-(\bar{x}, \bar{y}) \subseteq E(\bar{x}, \bar{y}, \bar{z})\),

and both \((M^+(\bar{x}, \bar{y}), M^-(\bar{x}, \bar{y}))\) and \(E(\bar{x}, \bar{y}, \bar{z})\) are built from \(N_C \cup N_R \cup \{\text{rdf: type}\} \cup N_I \cup \mathcal{F} \cup \mathcal{U} \cup \mathcal{Z}\).

A correction rule can be applied to a KB \(\mathcal{K}\) when there exist tuples of constants \(\bar{a}, \bar{b}\) such that \(\mathcal{K}\) violates \(\Gamma(\bar{d})\) (recall that this can be decided via CQ answering by Proposition 1) and \(\mathcal{K} \models \exists \bar{x}E(\bar{a}, \bar{b}, \bar{z})\). The result of the rule application is then \((M^+(\bar{a}, \bar{b}), M^-(\bar{a}, \bar{b}))\).

Note that while the variables from \(E(\bar{x}, \bar{y}, \bar{z})\) that do not appear in \(\Gamma(\bar{x})\) or in the head of \(r\) can be existentially quantified, those that occur in the head of \(r\) have to be free: they have to be mapped to individuals occurring in the KB in order to construct the result.

**Example 6:** In our running example, we would like to learn the following correction rules:

\[ r_1 := [\Gamma_0(\text{masculine})] : \langle \text{hasGender}(y, \text{masculine}) \rangle \rightarrow (\text{hasGender}(y, \text{male}), \text{hasGender}(y, \text{masculine})) \]

\[ r_2 := [\Gamma_2(x)] : \langle \text{hasMother}(y, x), \text{Human}(y) \rangle \rightarrow (\text{Human}(x), \emptyset) \]

The context of the second rule says that if \(x\) is the mother of a human, then \(x\) must also be a human. The rule obtained by replacing Human by Animal would express how to solve a violation of \(\Gamma_2\) in the context where \(y\) is an animal.

**Mining correction rules.** We mine correction rules with Algorithm 2. This algorithm is an adaptation of the algorithm in [13, 14] to our context, where we learn rules not from a KB but from the PCDataset and the KB history. We first adapt the definitions of the confidence and support from [13, 14] to our case. The support of the body of a correction rule \(r\) for a constraint \(\Gamma\) is the number of violations of \(\Gamma\) stored in the PCDataset that could have been corrected by applying \(r\). Such violations are associated with an instance \(\Gamma(\bar{d})\) of the partially instantiated \(\Gamma(\bar{x})\) that appears in \(r\) and with an index \(i\) such that \(\mathcal{K}_i \models \exists \bar{x}E(\bar{a}, \bar{b}, \bar{z})\) for some \(\bar{b}\). These two conditions imply that \(r\) could be applied to the KB \(\mathcal{K}_i\). Moreover, we need to check that the result of applying \(r\) to \(\mathcal{K}_i\) actually gives a solution to \(\mathcal{V}\). For example, consider the case where PCDataset contains both \(\langle(\emptyset, \text{R}(a, b)), \Gamma(a), \{\text{R}(a, b), \text{A}(a), i\}\rangle\) and \(\langle(\emptyset, \text{R}(a, c)), \Gamma(a), \{\text{R}(a, c), \text{A}(a), j\}\rangle\) for \(\Gamma(a) : \exists x \text{R}(a, x) \land \text{A}(a) \rightarrow \text{false}\). Both violations count for the support of the body of \([\Gamma(a) : \exists x \text{R}(a, x) \land \text{A}(a) \rightarrow \text{false}]\). Therefore, the support of the body of \(\Gamma(a) : \exists x \text{R}(a, x) \land \text{A}(a) \rightarrow \text{true}\) in the case where \(\mathcal{K}_i \models \text{R}(a, c)\).

Formally, \(\text{support}(r) = |B_{\text{Sup}}|\) where

\[ B_{\text{Sup}} = \{\mathcal{V} | \langle\langle \emptyset, \Gamma(\bar{d}), \mathcal{V}, i \rangle \in \text{PCDataset}, \exists \mathcal{K}_i \models \exists \bar{x}E(\bar{a}, \bar{b}, \bar{z})\text{ and the result of the application of }r\text{ to }\mathcal{K}_i\text{ is a solution to }\mathcal{V}\}. \]

**Table 2: Dataset PC Dataset of relevant past corrections extracted for our running example.**

<table>
<thead>
<tr>
<th>Relevant past correction</th>
<th>Constraint instance</th>
<th>Violation</th>
<th>KB index</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\langle\langle \text{Zeus}, \text{hasGender}, \text{male} \rangle, \langle \text{Zeus}, \text{hasGender}, \text{masculine} \rangle \rangle)</td>
<td>(\Gamma_0(\text{masculine}))</td>
<td>(\langle\langle \text{Zeus}, \text{hasGender}, \text{masculine} \rangle, \langle \text{Zeus}, \text{hasGender}, \text{male} \rangle \rangle)</td>
<td>100</td>
</tr>
</tbody>
</table>
The support of the rule \( r \) measures when the past correction is exactly the result of the application of the rule in the cases where it could be applied. Formally, \( \text{sup}_\text{rule}(r) = |\text{RSup}| \), where

\[
\text{RSup} = \{ \mathcal{V} \mid ((M^{+}(\overline{a}, \overline{b}), M^{-}(\overline{a}, \overline{b})), \Gamma(\overline{a}), \mathcal{V}, i) \in \text{PCDataset}, \quad \text{and } K_i \models \exists \mathcal{E}(\overline{a}, \overline{b}, \overline{z}) \}.
\]

Finally, the confidence of a correction rule \( r \) is \( \text{conf}(r) = \frac{\text{sup}_\text{rule}(r)}{\text{sup}_\text{rule}(r')}. \)

Algorithm 2 Correction rule mining

- **Input:** PCDataset, \((K_i)_{0 \leq i \leq p}, \text{minsup}, \text{minconf}, \theta\)
- **Output:** correction rules

  // Generate basic rules
  BasicR := \emptyset

  for all \((M^{+}(\overline{a}, \overline{b}), M^{-}(\overline{a}, \overline{b})), \Gamma(\overline{a}), \mathcal{V}, i) \in \text{PCDataset} \) do
  
  \( r_0 := [\Gamma(\overline{a})] : M^{+}(\overline{a}, \overline{b}) \rightarrow (M^{+}(\overline{a}, \overline{b}), M^{-}(\overline{a}, \overline{b})) \)

  BasicR := \{ \sigma(r_0) \mid C \subseteq \overline{a} \cup \overline{b}, \sigma : C \rightarrow \text{Var}, \text{sup}_\text{rule}(\sigma(r_0)) \geq \text{minsup}, \text{conf}(\sigma(r_0)) \geq \text{minconf} \}

  // Refine the context part of the rules
  q := [], q.enqueueAll(BasicR)

  while q is not empty do
  
  \( r := q.dequeue() \)

  for all operators \( op \) do
  
  for all \( r' \in op(r) \) do
  
  if \( \text{sup}_\text{rule}(r') \geq \text{minsup} \) and \( \text{conf}(r') \geq \text{conf}(r) + \theta \) then
  
  q.enqueue(r')

Applying correction rules. When all rules have been mined, they are sorted by decreasing confidence, breaking ties by help of the support (as it is done in [26] to build classifiers from rules). This set of rules then forms a program that can be used to fix constraint violations as follows. Given a violation \( \mathcal{V} \) of a constraint \( \Gamma \) in \( K \), choose the first rule \( r \) in the program that is relevant for \( \Gamma \) (i.e., that contains \( [\Gamma(\overline{x})] \) where \( \Gamma(\overline{x}) \) is a partially instantiated version of \( \Gamma \)). Then check whether \( r \) can be applied to \( \mathcal{V} \). The correction is the result of the rule application.

Example 7: Assume we mined the rules \( r_1 \) and \( r_2 \) of the preceding example with confidence 0.9 and 0.8 respectively, and another rule \( r_3 := [\Gamma_0(x)] : (\text{hasGender}(x, y)) \rightarrow (\emptyset, \text{hasGender}(x, y)) \) with confidence 0.5. The correction program is \((r_1, r_2, r_3)\). To correct a violation of \( \Gamma_0 \), i.e. a wrong value for the hasGender property, the program first checks whether \( r_1 \) is applicable. If so, it replaces masculine by male. Otherwise, it falls back to \( r_3 \) and removes the wrong value. To correct a violation of \( \Gamma_2 \), it ignores \( r_1 \) that is not related to \( \Gamma_2 \) and either applies \( r_2 \) if the context matches or does nothing.

7 EXPERIMENTS ON WIKIDATA

This section describes CorHist, which implements the framework introduced for Wikidata, and presents its experimental evaluation.

7.1 Wikidata

Wikidata is a generalist collaborative knowledge base. The project started in 2012, and as of July 2018, it has collected more than 500M statements about 50M entities. The data about each entity is stored in a versioned JSON blob, and there are more than 700M revisions. Wikidata encodes facts not in plain RDF triples but in a reified representation, in which each main \((s, p, o)\) triple can be annotated with qualifiers and provenance information [38].

Wikidata knows the property \text{instanceOf} which is similar to rdf: type. It does not have a formally defined TBox, but knows properties such as \text{subClassOf}, \text{subPropertyOf}, and \text{inverseOf}. However, only the property \text{subClassOf} is used to flag the constraint violations. Therefore, we use only this property in our TBox, which thus contains simple concept inclusions.

We consider the set \( C \) of constraints built from ten types of Wikidata property constraints (see Table 3). They are the top Wikidata property constraints that can be expressed in DL, covering the majority of the most used constraints, as well as 71% of Wikidata property constraints. The remaining constraints are mainly about string format validation with regular expressions (52% of the remaining constraints) and about qualifiers (31% of them).

7.2 Dataset Construction

We stored the RDF version [10, 18] of the Wikidata edit history in an RDF quad store. We used named graphs for the global state of Wikidata after each revision, and for the triple additions and deletions. Our dataset stores 390M annotated triples about 49M items extracted from the July 1st, 2018 full database dump.

We extracted the relevant past corrections as explained in Section 6.1. Wikidata revisions do not correspond exactly to atomic modifications in our sense. For example, Wikidata bots are able to change multiple unrelated facts about the same entity at the same
Table 3: Wikidata property constraints. $R$ is the property for which the constraint is given. A constraint has several lines when it uses a property whose set of values may be specified or not. $\#\text{constr.}$ is the total number of constraints of the given type in Wikidata. $\#\text{triples}$ is the sum for all these constraints of the numbers of triples with the property $R$ on which they apply. $\#\text{violations}$ is the number of violations for this constraint in Wikidata on July 1st, 2018. $\#\text{past cor.}$ is the number of past corrections we extracted from Wikidata history. t.o. indicates that we were not able to extract all past corrections because of timeout so that we sample them (we then indicate the number of corrections we extracted).

For each constraint. In practice, it affects only the most frequent 0.9% of Type, 2% of Value type, 0.5% of Item requires statement, and 3% of Value requires statement constraints.

7.3 Mining Rules

The output of our method is a set of correction rules that form a program (Section 6.2). To evaluate such a program, we apply it to each of the constraint violations stored in the PCDataset, using the associated stage of the KB to evaluate the part of the context which is not the deletion part of the correction. Then we check whether the correction we compute is exactly the same as the one associated to the constraint violation in the PCDataset. The precision $p$ of the program is given by the fraction of the corrections computed by the program that are actually the same as those that have been applied. The recall $r$ of the program is the fraction of the constraint violations stored in PCDataset for which the program gives some correction. The F1 score is $F_1 = 2\frac{p \cdot r}{p + r}$.

CorHist mines rules as explained in Section 6.2. In order to decrease the computation time, we only allow one atom $p(x,o)$ in $E(\vec{x}, \vec{y}, \vec{z}) \setminus \text{Body}(\vec{x}, \vec{y})$, where $\text{Body}(\vec{x}, \vec{y})$ corresponds to the part of the context that matches part of the constraint body, such that $s$ is a variable of $\vec{x} \cup \vec{y}$ and $o$ is a fresh variable or a constant.

Rules were mined per constraint. For each constraint, we split the set of extracted past corrections into a 70% training set, a 10% cross-validation set, and a 20% test set. The training set is used to mine the rules, the cross-validation set is used to determine the confidence threshold that maximizes the F1 score of the obtained program, and the test set is used to evaluate the final program.

Table 4 gives examples of rules mined by CorHist. Several of these rules show the crucial importance of the instantiation of the constraint and/or of the context to be able to choose the correction. For instance, the rule for the Single value constraint uses the fact that an entity involved in a property “member of sport team” is

$^4$ The Wikidata constraint Type can be qualified to modify its meaning. We ignore these cases, which are marginal: they concern less than 6% of the Type constraints.

$^5$ Inverse and Symmetric are two distinct kinds of constraints in Wikidata but we treat them together since Symmetric is actually a special case of Inverse.
probably a human being, and thus that if it has several values for the functional property “sex or gender” and one of them is a value reserved for non-human organisms in Wikidata, this value is probably wrong. In the same vein, the rule for the Item requires statement constraint recognizes that an entity has a heritage designation that is specific to Sweden (“monument in Formminnessregistret”), to conclude that its country is Sweden. The rules also propose fixes to misused predicates: in Wikidata, the property “manner of death” is intended for the general circumstances of a person’s death (such as “accident”), while the property “cause of death” is intended to give more precise causes (such as “traffic accident”).

7.4 Evaluation against the Test Set

Table 5 presents the results of the evaluation of the mined programs against the test set. We computed both the micro and macro average of the precision, recall and F1 score per kind of constraint. The micro average aggregates over the whole set of relevant past corrections for the given kind of constraint, whereas the macro average computes the scores for each constraint of this given kind, and then computes the average. Both numbers are important. The micro average gives more weight to correction rules that fix many violations. It thus measures the overall impact of the correction rules on the dataset. However, if few rules had a large impact, then it would be easier to formulate these rules by hand. Our method, in contrast, can also find rules that by themselves solve less violations, but together contribute a large mass of corrections. To illustrate this, we also report the macro average: It measures the average performance across different constraints.

We compare our approach with two baselines: The first one, called “delete”, is the most basic one and uses the fact that all Wikidata constraint bodies contain an atom of the form $R(x, y)$ and the TBox contains only concept inclusions, so that all constraint violations contain an assertion that matches $R(x, y)$. The “delete” baseline simply deletes this assertion. For the completeness constraints we define an additional baseline, “add”, which tries to add a new triple to solve the constraint violation. For Inverse and Symmetric constraints this baseline adds the missing reverse edge and performs very well. For Item requires statement, Value requires statement, Type and Value type, it adds the missing triple only if it is possible to know the expected value from the constraint rule.  

For example, for Type constraints of the form $\exists y R(x, y) \rightarrow A(x)$ it applies the correction $(A(x), \emptyset)$. Value type constraints are handled in the same way. However, this baseline is not able to figure out what is the relevant addition correction for a constraint of the form $\exists y R(x, y) \rightarrow A_1(x) \lor A_2(x)$ because there is no way to know a priori if $A_1$ or $A_2$ should be added. For Item requires statement constraints of the form $\exists y R(x, y) \rightarrow R'(x, a)$, the “add” baseline applies $(R'(x, a), \emptyset)$ (similarly for Value requires statement constraints). However, it cannot find a correction if there are multiple $a_i$.

$^6$Computed from a sample of the set of relevant past corrections. One Type constraint, six Value type constraints and one Val. req. stm constraint were omitted due to time-out.

$^7$The actual value is greater than 0.995 and rounded to 1 for consistency.
An entity should not have a statement for country of citizenship if it also has a statement for sex or gender with value male non-human organism.

### Possible correction

Edit statement (Q57082102, sex or gender, male non-human organism). Setting value to: male

Figure 1: Example of a replacement correction suggested by CorHist for a violation of the constraint ∃countryOfCitizenship ⊑ ¬∃sexOrGender · {maleOrg, femaleOrg}.

### 7.5 User Evaluation

To see whether our corrections are accepted by the community, we designed a user study. We created a tool that suggests our corrections for those kinds of constraints for which very few corrections have been evaluated. However, we can still make some interesting observations. In particular, the proposed corrections marked as wrong give us insights about possible weaknesses of our approach.

Table 6: Human evaluation of the suggested corrections.

</tbody>
</table>

As shown in Table 5, the precision of our approach significantly outperforms the two baselines – often by a very high margin. Regarding the recall, we manage to keep a reasonable, and sometimes even good, recall (see best F1 scores in Table 5), except for Single and Distinct value. The very low recall obtained for these two kinds of constraints is easily explainable because they are mostly used on predicates that link Wikidata to other databases (91% of the Single and 93% of the Distinct constraints), and we cannot get meaningful information about the target database to mine corrections.

### 8 CONCLUSION AND FUTURE WORK

We have introduced the problem of learning how to fix constraint violations from a KB history. We have also presented a method based on rule mining to this end. Our experimental evaluation on Wikidata shows significant improvement over baselines. Our tool is live on Wikidata and has already allowed users to correct more than 23k constraint violations. While our evaluation focused on Wikidata for which the whole edit history was available, we believe that our method can be applied in other settings, for example using edits done during the partial cleaning of an automatically extracted KB.

For future work, it would be interesting to evaluate the impact of parameters such as the size of the context part of the correction rule in terms of rule quality. We also plan to extend the learning dataset with external knowledge (such as other KBs), or with information extracted from other sources (for instance from Wikipedia). We believe that this will allow finding even more precise correction rules, thus making KBs ever more precise and more useful.
